GlucoTwin continuous architecture

An auditable reading-to-review workflow with separate source and clinical release gates

Shared persistence: SQLite research / Alembic-managed PostgreSQL research; metadata-only SSE outbox.

Trust boundary

Measurement, source availability, server receipt, input cutoff, issuance, target and human-action times remain distinct. Backfill cannot rewrite saved evidence. Scoped connector credentials bind device events to one patient; patient access exposes only its own permitted records.

Evidence boundary

The pipeline is verified locally with synthetic arrivals and recorded public-data cases. Real wearable integration, clinician feedback, a prospective shadow study, always-on private hosting and clinical release remain pending.
